Groundwater discharging from a dolomite aquifer as a spring is an example of a karst spring. The springs are located where the dolomite intersects the land surface, allowing the water to flow above the water table. As the Dry season progresses, the area of shallow groundwater which accumulates in the depression caused by this subsidence. Groundwater occurs in both depressions caused by this subsidence. Groundwater occurs in both

The aquifer tapped by Peels Well is a shallow dolomite aquifer established. The aquifer tapped by Peels Well is a shallow dolomite aquifer. It contains calcium, magnesium, and carbonate which are determined from the rock.

Detailed analysis of the data shows that the creek flow is main-
